

### Introduction

Products of normal chemical metabolism may be altered in schizophrenia. Changes in metabolite levels may be indicative of altered biochemical activity. Magnetic resonance spectroscopy (MRS) has been used to measure levels of metabolites, such as N-acetylaspartate (NAA), creatine (Cr), trimethylamines/ choline containing compounds (Cho) and glutamine (Gln). These derivatives are indirect indicators of biochemical activity. Alteration in levels of NAA/Cr is associated with the protective myelin sheath surrounding neurons, which is used as a marker of neural cell viability. Decreased levels of NAA are associated with neuron death, or injury to the part of the neuron that connects to other cells, the axon. Gln is a metabolite of the neurotransmitter, glutamate (Glu).

### Method

We have included only systematic reviews (systematic literature search, detailed methodology with inclusion/exclusion criteria) published in full text, in English, from the year 2000 that report results separately for people with a diagnosis of schizophrenia, schizoaffective disorder, schizophreniform disorder or first episode schizophrenia. Reviews were identified by searching the databases MEDLINE, EMBASE, CINAHL, Current Contents, PsycINFO and the Cochrane library. Hand searching reference lists of identified reviews was also conducted. When multiple copies of reviews were found, only the most recent version was included. Reviews with pooled data are prioritised for inclusion.

Review reporting assessment was guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses ([PRISMA](#)) checklist, which describes a preferred way to present a meta-analysis<sup>1</sup>. Reviews rated as having less than 50% of items checked have been excluded from the library. The PRISMA flow diagram is a suggested way of providing information about studies included and

excluded with reasons for exclusion. Where no flow diagram has been presented by individual reviews, but identified studies have been described in the text, reviews have been checked for this item. Note that early reviews may have been guided by less stringent reporting checklists than the PRISMA, and that some reviews may have been limited by journal guidelines.

Evidence was graded using the Grading of Recommendations Assessment, Development and Evaluation ([GRADE](#)) Working Group approach where high quality evidence such as that gained from randomised controlled trials (RCTs) may be downgraded to moderate or low if review and study quality is limited, if there is inconsistency in results, indirect comparisons, imprecise or sparse data and high probability of reporting bias. It may also be downgraded if risks associated with the intervention or other matter under review are high. Conversely, low quality evidence such as that gained from observational studies may be upgraded if effect sizes are large, there is a dose dependent response or if results are reasonably consistent, precise and direct with low associated risks (see end of table for an explanation of these terms)<sup>2</sup>. The resulting table represents an objective summary of the available evidence, although the conclusions are solely the opinion of staff of NeuRA (Neuroscience Research Australia).

### Results

We found nine systematic reviews that met our inclusion criteria<sup>3-11</sup>.

- Moderate or moderate to high quality evidence suggests NAA levels (measured as both NAA and NAA/Cr) are decreased in people with schizophrenia in the frontal lobe, temporal lobe, thalamus, hippocampus, cerebellum, cingulate cortex.

## Neurometabolites

- Moderate to low quality evidence suggests that NAA may also be decreased in the parietal cortex, basal ganglia and occipital lobe (white matter only). NAA may be increased in the striatum and lenticular nucleus.
- Moderate quality evidence suggests there are NAA reductions in the anterior cingulate and hippocampus of first-degree relatives of people with schizophrenia. People at clinical or genetic high-risk of schizophrenia showed NAA reductions in the thalamus and NAA/Cr ratio reductions in the prefrontal cortex.
- Moderate to low quality evidence suggests small to medium-sized reductions in glutamate and increases in glutamine levels in the frontal cortex of people with schizophrenia compared to controls, which may progress with age. Low quality evidence is unclear about hippocampus and thalamic levels.

<b>Comparison</b>	<b>Glutamatergic metabolite levels (measured by MRS) in children or youth with schizophrenia or with parent with schizophrenia vs. controls.</b>
-------------------	--

<b>Summary of evidence</b>	<b>Low quality evidence (small samples, direct, unable to assess precision or consistency) is uncertain of glutamatergic metabolite levels in children or youth with schizophrenia or with parent with schizophrenia.</b>
<b>Glutamatergic metabolites</b>	
<p>1 study (N = 42) reported increased glutamate+glutamine/creatine ratio in the right medial frontal lobe of youth (mean age 16.4 years) with a parent with schizophrenia. Increased ratio levels correlated with poorer functioning levels assessed by the Global Assessment of Functioning scale. There were no differences in NAA/creatine, inositol-containing compounds/creatine or choline compounds/creatine.</p> <p>1 study (N = 86) reported increased glutamate+glutamine in the inferior parietal/occipital cortex of youth (mean age 15.6 years) with a parent with schizophrenia or schizoaffective disorder. Glutamate+glutamine levels correlated negatively in high-risk youth (older age = lower levels), and positively in controls (older age = increased levels). No differences were found in glutamate+glutamine levels the caudate, prefrontal white matter, anterior cingulate cortex, superior temporal region, or posterior white matter. There were also decreased NAA, choline compounds, creatine and phosphocreatine levels in the caudate and increased NAA in prefrontal white matter in a subgroup of youth at at-risk for schizophrenia that were without psychopathology. There were no differences in NAA, choline compounds, creatine or phosphocreatine levels in the anterior cingulate cortex, thalamus, inferior parietal/occipital cortex, or superior temporal region.</p> <p>1 study (N = 47) reported increased glutamate+glutamine and decreased NAA in the left and right thalamus and caudate of youth with a parent with schizophrenia (mean age 15.9 years). Positive correlations between these increases and attenuated psychotic symptoms (increased metabolites = increased symptoms), and perseverative errors on the Wisconsin Card Sorting Test were reported. Reduced NAA and increased choline compounds were found in the anterior cingulate cortex.</p> <p>1 study (N = 25) found decreased glutamate+glutamine/creatine ratio in in occipital and frontal lobes (trend effect for frontal lobes) of children with schizophrenia (mean age 14 years). There was also reduced NAA/creatine in the frontal lobes, and no differences in NAA/creatine in the occipital lobes. There were no differences in choline compounds/creatine or mlno/creatine.</p> <p>1 study (N = 41) found no differences in glutamatergic metabolites in the inferior and middle frontal and superior temporal gyri between children with schizophrenia (mean age 14 years) and controls (mean age 11.5 years).</p>

[View review abstract online](#)

<b>Comparison</b>	<b>Comparison of metabolic NAA activity (measured by <sup>1</sup>H-MRS) in the hippocampus of schizophrenia patients vs. healthy controls</b> <b>Compares the consistency of measuring NAA as a raw percentage to measuring as a ratio with control data</b>
<b>Summary of evidence</b>	<b>Moderate to low quality evidence (sample size unclear, direct inconsistent, unable to assess precision) suggests that NAA may be decreased in the frontal cortex, temporal cortex, hippocampus, anterior cingulate, cerebellum, parietal cortex, thalamus, basal ganglia and occipital lobe white matter. NAA may be increased in the striatum and lenticular nucleus.</b>

**NAA/Cr**

Frontal cortex

Grey matter: 25 (N unclear), patient average NAA 94.2% of control levels  
White matter: 18 (N unclear), patient average NAA 94.8% of control levels

Temporal cortex

Grey matter: 5 (N unclear), patient average NAA 94.0% of control levels  
White matter: 8 (N unclear), patient average NAA 87.3% of control levels

Hippocampus

All: 8 studies (N = 305), patient average NAA/Cr 88.8% of control levels  
All: 5 studies (N = 248), patient average NAA/Cr 85.8% of control levels  
Grey matter: 17 studies (N unclear), NAA 88.9% of control levels

Anterior cingulate gyrus

Grey matter: 12 studies (N unclear), patient average NAA 95.9% of control levels

Cerebellum

Grey matter: 3 studies (N unclear), patient average NAA 92.3% of control levels

Parietal cortex

Grey matter: 1 study (N unclear), patient average NAA 94.0% of control levels  
White matter: 2 studies (N unclear), patient average NAA 99.0% of control levels

Thalamus

**Neurometabolites**

**SCHIZOPHRENIA LIBRARY**

Grey matter: 19 studies (N unclear), patient average NAA 96.5% of control levels

Basal ganglia

Grey matter: 6 studies (N unclear), patient average NAA 98.5% of control levels

Occipital cortex

White matter: 1 study (N unclear), patient average NAA 96.0% of control levels

Grey matter: 8 studies (N unclear), patient average NAA 102.8% of control levels

Striatum (caudate + putamen)

Grey matter: 1 study (N unclear), patient average NAA 112.6% of control levels

Lenticular nucleus (putamen + globus pallidus)

Grey matter: 2 studies (N unclear), patient average NAA 104.5% of control levels

Posterior cingulate

Grey matter: 5 studies (N unclear), patient average NAA 100% of control levels

Caudate nucleus

Grey matter: 3 studies (N unclear), patient average NAA 100.3% of control levels

Putamen

Grey matter: 7 studies (N unclear), patient average NAA 100.6% of control levels

Centrum semiovale

White matter: 5 studies (N unclear), patient average NAA 100.2% of control levels

<b>Consistency in results</b>	Significant heterogeneity reported, $p < 0.0001$
<b>Precision in results</b>	Precise, CIs reasonably stringent
<b>Directness of results</b>	Direct measures and comparison of NAA levels.

**Explanation of acronyms**

CI = Confidence Interval, Cr = Creatine amino acid, DLPFC = dorsolateral prefrontal cortex, Gln = glutamine (glutamate synaptic metabolic), Glu = glutamate neurotransmitter, <sup>1</sup>H-MRS = Proton Magnetic Resonance Spectroscopy, LS = Least Squares mean, N = number of participants, NAA =

Neurometabolites

N-acetylaspartate amino acid, NAA/Cr = ratio of NAA and Cr,  $p$  = statistical probability of obtaining that result ( $p < 0.05$  generally regarded as significant),  $^{31}\text{P}$ -MRS = Phosphorus Magnetic Resonance Spectroscopy, PDE = phosphodiester lipid, PME = phosphomonoester lipid, U = units

### Explanation of technical terms

\* Bias has the potential to affect reviews of both RCT and observational studies. Forms of bias include; reporting bias that involves the selective reporting of results; publication bias - trials that are not formally published tend to show less effect than published trials, further if there are statistically significant differences between groups in a trial, these trial results tend to get published before those of trials without significant differences; language bias – only including English language reports; funding bias - source of funding for the primary research with selective reporting of results within primary studies; outcome variable selection bias; database bias - including reports from some databases and not others; citation bias - preferential citation of authors. Trials can also be subject to bias when evaluators are not blind to treatment condition and selection bias of participants if trial samples are small.

† Different effect measures are reported by different reviews.

Weighted mean difference scores refer to mean differences between treatment and comparison groups after treatment (or occasionally pre to post treatment) and in a randomized trial there is an assumption that both groups are comparable on this measure prior to treatment. Standardised mean differences are divided by the pooled standard deviation (or the standard deviation of one group when groups are homogenous) which allows results from different scales to be combined and compared. Each study's mean difference is then given a weighting depending on the size of the sample and the variability in the data. 0.2 represents a small

effect, 0.5 a medium effect, and 0.8 and over represents a large effect<sup>12</sup>.

Reliability and validity refers to how accurate the instrument is. Sensitivity is the proportion of actual positives that are correctly identified (100% sensitivity = correct identification of all actual positives) and specificity is the proportion of negatives that are correctly identified (100% specificity = not identifying anyone as positive if they are truly not).

Odds ratio (OR) or relative risk (RR) refers to the probability of a reduction ( $< 1$ ) or an increase ( $> 1$ ) in a particular outcome in a treatment group, or a group exposed to a risk factor, relative to the comparison group. For example, a RR of 0.75 translates to a reduction in risk of an outcome of 25% relative to those not receiving the treatment or not exposed to the risk factor. Conversely, a RR of 1.25 translates to an increased risk of 25% relative to those not receiving treatment or not having been exposed to a risk factor. A RR or OR of 1.00 means there is no difference between groups. A medium effect is considered if  $RR > 2$  or  $< 0.5$  and a large effect if  $RR > 5$  or  $< 0.2$ <sup>13</sup>. InOR stands for logarithmic OR where a InOR of 0 shows no difference between groups. Hazard ratios measure the effect of an explanatory variable on the hazard or risk of an event.

Correlation coefficients (eg,  $r$ ) indicate the strength of association or relationship between variables. They are an indication of prediction, but do not confirm causality due to possible and often unforeseen confounding variables. An  $r$  of 0.10 represents a weak association, 0.25 a medium association and 0.40 and over represents a strong association. Unstandardised ( $b$ ) regression coefficients indicate the average change in the dependent variable associated with a 1 unit change in the independent variable, statistically controlling for the other

## Neurometabolites

## SCHIZOPHRENIA LIBRARY

independent variables. Standardised regression coefficients represent the change being in units of standard deviations to allow comparison across different scales.

Prevalence refers to how many existing cases there are at a particular point in time. Incidence refers to how many new cases there are per population in a specified time period. Incidence is usually reported as the number of new cases per 100,000 people per year. Alternatively some studies present the number of new cases that have accumulated over several years against a person-years denominator. This denominator is the sum of individual units of time that the persons in the population are at risk of becoming a case. It takes into account the size of the underlying population sample and its age structure over the duration of observation.

---

‡ Inconsistency refers to differing estimates of treatment effect across studies (i.e. heterogeneity or variability in results) that is not explained by subgroup analyses and therefore reduces confidence in the effect estimate.  $I^2$  is the percentage of the variability in effect estimates that is due to heterogeneity rather than sampling error (chance) - 0% to 40%: heterogeneity might not be important, 30% to 60%: may represent moderate heterogeneity, 50% to 90%: may represent considerable heterogeneity and over this is considerable heterogeneity.  $I^2$  can be calculated from Q (chi-square) for the test of heterogeneity with the following formula;

$$I^2 = \left( \frac{Q - df}{Q} \right) \times 100\%$$

§ Imprecision refers to wide confidence intervals indicating a lack of confidence in the effect estimate. Based on GRADE recommendations, a result for continuous data (standardised mean differences, not weighted mean differences) is considered imprecise if the upper or lower confidence limit crosses an effect size of 0.5 in either direction, and for binary and correlation data, an effect size of 0.25. GRADE also recommends downgrading the evidence when sample size is smaller than 300 (for binary data) and 400 (for continuous data), although for some topics, this criteria should be relaxed<sup>14</sup>.

---

|| Indirectness of comparison occurs when a comparison of intervention A versus B is not available but A was compared with C and B was compared with C, which allows indirect comparisons of the magnitude of effect of A versus B. Indirectness of population, comparator and or outcome can also occur when the available evidence regarding a particular population, intervention, comparator, or outcome is not available so is inferred from available evidence. These inferred treatment effect sizes are of lower quality than those gained from head-to-head comparisons of A and B.
