

Post-traumatic stress disorder

Introduction

The Diagnostic and Statistical Manual of Mental Disorders' (DSM-5) criteria for a diagnosis of post-traumatic stress disorder (PTSD) includes having been exposed to a trauma via direct means (e.g. threats, experience, or witnessing), or indirect means (e.g. learning that a relative or close friend has been exposed to a trauma).

For a diagnosis of PTSD, symptoms must last for more than one month and create distress and functioning impairment such as an inability to work, go to school, or socialise. Symptoms include persistently re-experiencing the traumatic event via intrusive thoughts, nightmares, or flashbacks. These can be brought on with exposure to traumatic reminders and are associated with emotional distress. As a result, avoidance of trauma-related stimuli occurs. There is often an inability to recall key features of the trauma.

Other symptoms include negative thoughts and assumptions about oneself or the world, exaggerated blame of self or others for causing the trauma, negative affect, decreased interest in activities, feelings of isolation, irritability or aggression, risky or destructive behavior, hypervigilance, heightened startle reaction, and difficulty concentrating and sleeping.

Method

We have included only systematic reviews (systematic literature search, detailed methodology with inclusion/exclusion criteria) published in full text, in English, from the year 2010 that report results separately for people with a diagnosis of bipolar or related disorders. Reviews were identified by searching the databases MEDLINE, EMBASE, and PsycINFO. Hand searching reference lists of identified reviews was also conducted. When multiple copies of review topics were found, only the most recent and/or comprehensive review was included. Reviews with pooled data were prioritised for inclusion.

Review reporting assessment was guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) checklist that describes a preferred way to present a meta-analysis¹. Reviews with less than 50% of items checked have been excluded from the library. The PRISMA flow diagram is a suggested way of providing information about studies included and excluded with reasons for exclusion. Where no flow diagram has been presented by individual reviews, but identified studies have been described in the text, reviews have been checked for this item. Note that early reviews may have been guided by less stringent reporting checklists than the PRISMA, and that some reviews may have been limited by journal guidelines.

Evidence was graded using the Grading of Recommendations Assessment, Development and Evaluation ([GRADE](#)) Working Group approach where high quality evidence such as that gained from randomised controlled trials (RCTs) may be downgraded to moderate or low if review and study quality is limited, if there is inconsistency in results, indirect comparisons, imprecise or sparse data and high probability of reporting bias. It may also be downgraded if risks associated with the intervention or other matter under review are high. Conversely, low quality evidence such as that gained from observational studies may be upgraded if effect sizes are large or if there is a dose dependent response. We have also taken into account sample size and whether results are consistent, precise and direct with low associated risks (see end of table for an explanation of these terms)². The resulting table represents an objective summary of the available evidence, although the conclusions are solely the opinion of staff of NeuRA (Neuroscience Research Australia).

Post-traumatic stress disorder

Results

We found three systematic reviews that met our inclusion criteria³⁻⁵.

- Moderate quality evidence suggests the lifetime prevalence of PTSD in people with bipolar I disorder or bipolar II disorder is around 17%.
- Moderate quality evidence suggests the current prevalence of PTSD in people with bipolar disorder during euthymia is around 3%.
- Moderate to low quality evidence suggests cognitive behavioural therapy may be effective for improving PTSD symptoms in people with bipolar disorder.

Prevalence of current anxiety disorders in people with bipolar disorder during euthymia: a meta-analysis

Psychological Medicine 2017; 47: 1107-15

[View review abstract online](#)

Comparison	Prevalence of PTSD in people with bipolar disorder during euthymia.
Summary of evidence	Moderate quality evidence (large samples, inconsistent, imprecise, direct) suggests the current prevalence of PTSD in

Post-traumatic stress disorder

	people with bipolar disorder during euthymia is around 3%.
PTSD	
Current prevalence: 9 studies, N = 2,011, 2.9%, 95%CI 0.5% to 5.4%	
Consistency in results	Authors report results are inconsistent.
Precision in results	Imprecise
Directness of results	Direct

Stratford HJ, Cooper MJ, Di Simplicio M, Blackwell SE, Holmes EA

Psychological therapy for anxiety in bipolar spectrum disorders: a systematic review

Clinical Psychology Review 2015; 35: 19-34

[View review abstract online](#)

Comparison	Cognitive behavioural therapy (CBT) or psychoeducation for PTSD symptoms in people with bipolar disorder.
Summary of evidence	Moderate to low quality evidence (small samples, appears consistent, unable to assess precision, direct) suggests cognitive behavioural therapy may be effective for improving PTSD symptoms in people with bipolar disorder.
PTSD	
<p><i>CBT resulted in reduced PTSD symptoms in the following studies;</i></p> <p>1 controlled study, N = 25 people with bipolar disorder and PTSD (12-16 x 1hr weekly CBT vs. treatment as usual).</p> <p>1 pilot, N = 14 people with bipolar disorder and PTSD (12-16 x 1hr weekly CBT).</p> <p>1 pilot, N = 7 people with bipolar disorder and PTSD (21 sessions of group CBT).</p> <p>1 pilot, N = 2 people with bipolar disorder and PTSD (12-16 x 1hr weekly CBT).</p> <p>1 case study with bipolar disorder and PTSD (12 sessions over 10 weeks of CBT).</p>	
Consistency in results	Appears consistent
Precision in results	Unable to assess; no CIs are reported.

Post-traumatic stress disorder

Directness of results	Direct
------------------------------	--------

Explanation of acronyms

CBT = Cognitive Behavioural Therapy, CI = Confidence Interval, N = number of participants, p = statistical probability of obtaining that result ($p < 0.05$ generally regarded as significant), RR = risk ratio, vs. = versus

Post-traumatic stress disorder

Explanation of technical terms

* Bias has the potential to affect reviews of both RCT and observational studies. Forms of bias include; reporting bias – selective reporting of results; publication bias - trials that are not formally published tend to show less effect than published trials, further if there are statistically significant differences between groups in a trial, these trial results tend to get published before those of trials without significant differences; language bias – only including English language reports; funding bias - source of funding for the primary research with selective reporting of results within primary studies; outcome variable selection bias; database bias - including reports from some databases and not others; citation bias - preferential citation of authors. Trials can also be subject to bias when evaluators are not blind to treatment condition and selection bias of participants if trial samples are small⁶.

† Different effect measures are reported by different reviews.

Prevalence refers to how many existing cases there are at a particular point in time. Incidence refers to how many new cases there are per population in a specified time period. Incidence is usually reported as the number of new cases per 100,000 people per year. Alternatively some studies present the number of new cases that have accumulated over several years against a person-years denominator. This denominator is the sum of individual units of time that the persons in the population are at risk of becoming a case. It takes into account the size of the underlying population sample and its age structure over the duration of observation.

Reliability and validity refers to how accurate the instrument is. Sensitivity is the proportion

of actual positives that are correctly identified (100% sensitivity = correct identification of all actual positives) and specificity is the proportion of negatives that are correctly identified (100% specificity = not identifying anyone as positive if they are truly not).

Weighted mean difference scores refer to mean differences between treatment and comparison groups after treatment (or occasionally pre to post treatment) and in a randomised trial there is an assumption that both groups are comparable on this measure prior to treatment. Standardised mean differences are divided by the pooled standard deviation (or the standard deviation of one group when groups are homogenous) that allows results from different scales to be combined and compared. Each study's mean difference is then given a weighting depending on the size of the sample and the variability in the data. Less than 0.4 represents a small effect, around 0.5 a medium effect, and over 0.8 represents a large effect⁶.

Odds ratio (OR) or relative risk (RR) refers to the probability of a reduction (< 1) or an increase (> 1) in a particular outcome in a treatment group, or a group exposed to a risk factor, relative to the comparison group. For example, a RR of 0.75 translates to a reduction in risk of an outcome of 25% relative to those not receiving the treatment or not exposed to the risk factor. Conversely, a RR of 1.25 translates to an increased risk of 25% relative to those not receiving treatment or not having been exposed to a risk factor. A RR or OR of 1.00 means there is no difference between groups. A medium effect is considered if $RR > 2$ or < 0.5 and a large effect if $RR > 5$ or < 0.2 ⁷. InOR stands for logarithmic OR where a InOR of 0 shows no difference between groups. Hazard ratios measure the effect of an explanatory variable on the hazard or risk of an event.

Post-traumatic stress disorder

Correlation coefficients (eg, r) indicate the strength of association or relationship between variables. They can provide an indirect indication of prediction, but do not confirm causality due to possible and often unforeseen confounding variables. An r of 0.10 represents a weak association, 0.25 a medium association and 0.40 and over represents a strong association. Unstandardised (b) regression coefficients indicate the average change in the dependent variable associated with a 1 unit change in the independent variable, statistically controlling for the other independent variables. Standardised regression coefficients represent the change being in units of standard deviations to allow comparison across different scales.

‡ Inconsistency refers to differing estimates of effect across studies (i.e. heterogeneity or variability in results) that is not explained by subgroup analyses and therefore reduces confidence in the effect estimate. I^2 is the percentage of the variability in effect estimates that is due to heterogeneity rather than sampling error (chance) - 0% to 40%: heterogeneity might not be important, 30% to 60%: may represent moderate heterogeneity, 50% to 90%: may represent considerable heterogeneity and over this is considerable heterogeneity. I^2 can be calculated from Q (chi-square) for the test of heterogeneity with the following formula⁶;

$$I^2 = \left(\frac{Q - df}{Q} \right) \times 100\%$$

§ Imprecision refers to wide confidence intervals indicating a lack of confidence in the effect estimate. Based on GRADE recommendations, a result for continuous

data (standardised mean differences, not weighted mean differences) is considered imprecise if the upper or lower confidence limit crosses an effect size of 0.5 in either direction, and for binary and correlation data, an effect size of 0.25. GRADE also recommends downgrading the evidence when sample size is smaller than 300 (for binary data) and 400 (for continuous data), although for some topics, these criteria should be relaxed⁸.

|| Indirectness of comparison occurs when a comparison of intervention A versus B is not available but A was compared with C and B was compared with C that allows indirect comparisons of the magnitude of effect of A versus B. Indirectness of population, comparator and/or outcome can also occur when the available evidence regarding a particular population, intervention, comparator, or outcome is not available and is therefore inferred from available evidence. These inferred treatment effect sizes are of lower quality than those gained from head-to-head comparisons of A and B.
